Good food shouldn’t end up as waste.

LastTray

Good food deserves a second chance.

Group 3: Siya, Chetna Gupta, Rahel, Shatakshi, Shivani Rajpoot, Khushi, Anjali Krishna & Sandhya Kumari

Illustrative app mock-up

THE PROBLEM

Surplus and demand miss each other at closing time.

The merchant Suitable food stays unsold when demand falls short of expectations.

The customer Price-conscious customers want affordable food but cannot easily discover nearby surplus.

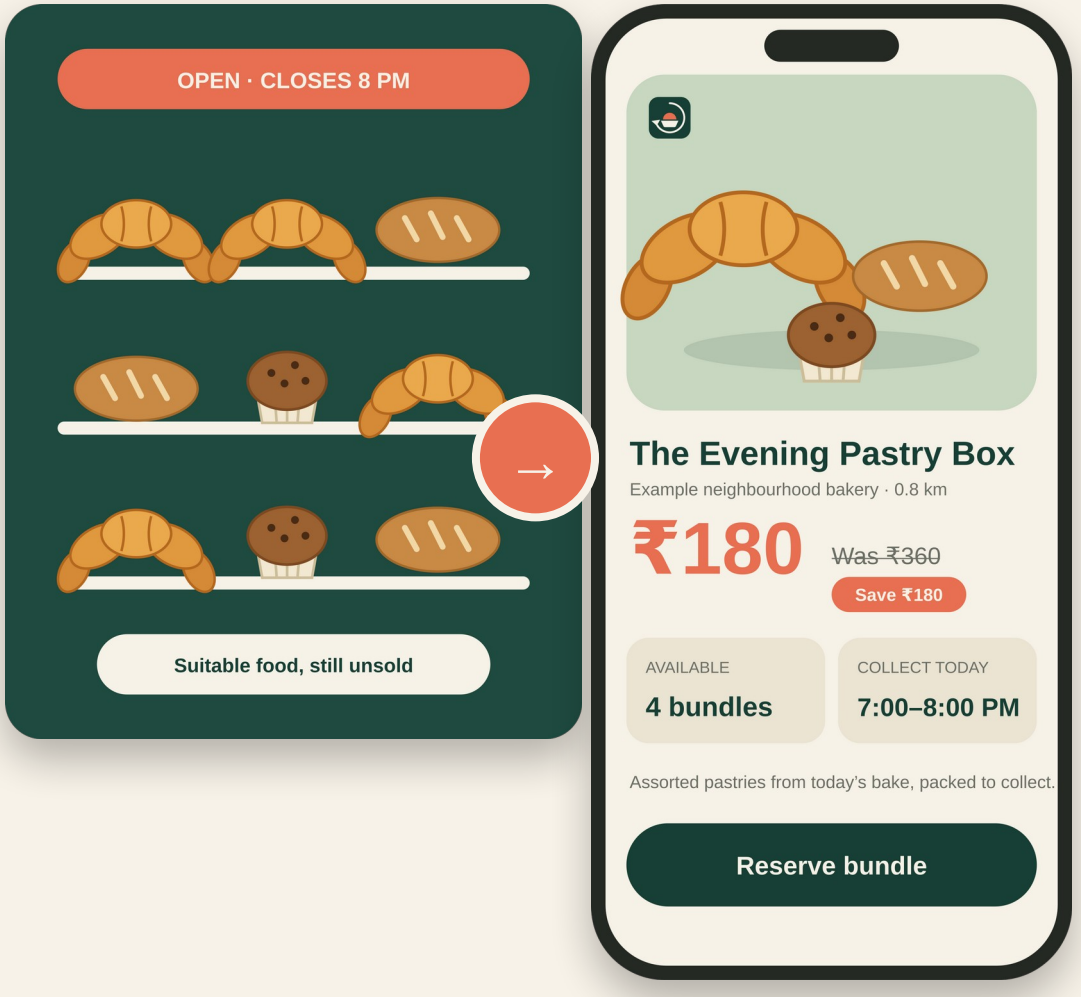

The opportunity LastTray connects surplus with nearby customers before the selling window closes.

Why it persists: demand fluctuates, forecasting cannot remove all uncertainty, and perishable food has a short selling window.

First customers: independent bakeries and cafés in one Delhi NCR neighbourhood. Proposed pilot target, not a result: 10–15 merchants. Revenue: commission on completed orders.

1 THE BAKERY

2 THE CUSTOMER

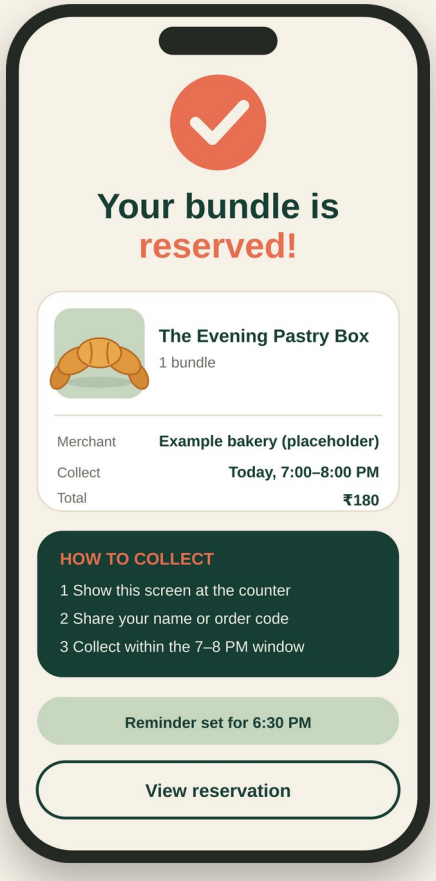

Proposed product concept: illustrative mock-up and drawn graphics, not a live app or a real merchant.

UNIT ECONOMICS · ONE COMPLETED ORDER

Every order must make economic sense.

Why one order: LastTray earns a commission per completed order and incurs identifiable variable costs on each one.

1

₹180

Customer order

merchant's sale value

2

The ₹180 is the merchant's sale, not LastTray's revenue. Our revenue is only the ₹36 commission.

₹36

Platform revenue

₹180 × 20% = ₹36

3

₹23 is what remains for fixed costs and profit.

–₹13

Variable cost

₹5 payment + ₹8 support & ops

4

₹23

Contribution

₹36 − ₹13 = ₹23

ILLUSTRATIVE ASSUMPTIONS, NOT ACTUAL RESULTS. App screen is an illustrative mock-up.

LTV · CAC · BREAK-EVEN

Repeat customers determine the economics.

Downside

1.15 : 1

1.5 orders/mo × 4 mo = 6 orders

₹138

Contribution LTV

CAC ₹120 (assumed)

Base

2.3 : 1

2 orders/mo × 6 mo = 12 orders

₹276

Contribution LTV

CAC ₹120 (assumed)

Upside

2.9 : 1

2.5 orders/mo × 6 mo = 15 orders

₹345

Contribution LTV

CAC ₹120 (assumed)

Break-even: ₹1,15,000 ÷ ₹23 = 5,000 orders a month, about 167 a day

LTV rises or falls with repeat frequency, retention, contribution margin, acquisition cost and merchant availability. Base LTV = 12 × ₹23 = ₹276; ₹276 ÷ ₹120 = 2.3.

Illustrative assumptions, simplified outputs. Break-even counts only the assumed ₹1,15,000 monthly fixed costs and ₹13 variable cost; other costs are excluded.

TAKEAWAY

Start local. Prove repeat demand. Scale only when the economics work.

Illustrative packaging concept

Bakery lists surplus → Customer reserves → Customer collects → LastTray earns commission

01 The problem

LastTray addresses a plausible problem for food businesses and price-conscious customers.

02 The economics

Viability depends on validating merchant participation, repeat purchases and contribution per order before scaling.

Good food deserves a second chance.
